Decision Document Solid Waste Management Unit C01a/01b Building 102-31 Rotary Deactivation Furnaces

August 2001

Decision Document SWMU C01a/01b

August 2001

The selected remedy is protective of human health and the environment. It has been shown that exposure to the chemicals of concern at this SWMU has been mitigated to the level that is nonhazardous to human health and the environment, and there is no potential for an exposure to these chemicals in the future.

Decision Document SWMU C01a/01b Building 102-31 Rotary Deactivation Furnaces Hawthorne Army Depot Hawthorne, Nevada August 2001

1.0 INTRODUCTION

This decision document describes the rationale for the proposed closure of solid waste management unit (SWMU) C01a/01b at the Hawthorne Army Depot (HWAD), Hawthorne, Nevada (Figure 1-1). This SWMU is the former site of two deactivation furnaces used for demilitarizing small arms ammunition, primers, and fuses. Tetra Tech, Inc. (Tt) prepared this decision document for the US Army Corps of Engineers, Sacramento District (USACE), with guidance from HWAD for submittal and approval by the Nevada Department of Environmental Protection (NDEP).

Tt has performed remedial investigations and groundwater monitoring at HWAD since 1993, primarily at SWMUs designated by the Army and the NDEP. The purpose of the sampling was to determine the extent and degree of environmental impacts, if any, associated with activities performed at each SWMU. The primary goal of the investigation was to assess the environmental impacts and to report the findings, to present conclusions, and to recommend remediation, if necessary.

With guidance from the NDEP, Tt established basewide proposed closure goals (PCGs) as acceptable levels for soil so that HWAD could recommend SWMU closure, and to help direct the investigative efforts toward those SWMUs where the target analytes were of greatest concern. Also, HWAD-specific groundwater action levels were established as acceptable concentrations to determine if further action would be required to remediate analytes of concern in the groundwater. Following Tt's evaluation of the investigation results and after completing a site-specific risk assessment, remediation goals for this SWMU were recommended which the NDEP approved. The PCGs and remediation goals are included in Appendix A.

2.0 SITE HISTORY

SWMU C01a/01b is in HWAD's central magazine area, east of Thorne Road and within the 102 Magazine Group (Figure 1-1). This SWMU was the site of two rotary deactivation furnaces on the northern and southern ends of Building 102-31 (Figure 1-2). Both furnaces were installed on concrete pads measuring approximately 35 feet wide by 55 feet long.

The USACE, HWAD, and the NDEP agreed to define the boundaries of each SWMU using annotated monuments and survey pins. As part of our field investigation, we surveyed SWMU C01a/01b and constructed two survey monuments. A brass survey pin on each monument designates them as HWAAP-51-1996 and HWAAP-63-1996 and includes the SWMU number C01a/01b. four corner pins were set and surveyed to define the SWMU boundary, with

monument HWAAP-51-1996 near the south corner and monument HWAAP-63-1996 near the north corner. The location of these corner markers and the SWMU boundary are shown on Figure 1-2. Survey data is presented in Appendix B.

The current depth to groundwater in the vicinity of SWMU C01a/01b at approximately 100 feet below ground surface (bgs) based on the data reported in the 2000 annual groundwater report (Tt 2001).

3.0 SITE CONDITIONS

The United States Army Environmental Hygiene Agency (USAEHA) (1988), RAI (1992), and Jacobs Engineering (1988) have inspected SWMU C01a/01b. During its inspection, USAEHA noted that the furnaces appeared clean and that there was a small amount of soot and ash near the baghouse hoppers and feed chains at both incinerators.

Tt inspected SWMU C01a/01b in November 1993. The incinerators were inside unroofed enclosures constructed from ten-foot-high metal ammunition boxes. The incinerators were mounted so that material could be fed from inside Building 102-31. The exhaust stacks and baghouses were outside the enclosures, with entrances along the southern walls. Most of the furnace and associated equipment, including the baghouses, were dismantled and removed. There were scattered expended small arms rounds, shell casings, and fragments of slag on the ground, mostly on the north, south, and east sides of the building.

4.0 INVESTIGATIONS

From 1994 through 1997, Tt collected 231 surface soil samples and 19 duplicate surface soil samples at SWMU C01a/01b and had them analyzed for lead. Two hundred and eighteen of these 231 soil samples contained lead concentrations exceeding the HWAD PCG of 100 mg/kg, with a maximum concentration of 200,000 mg/kg (the 100 mg/kg for lead was in place at the time the initial remedial investigation occurred, since that time the standard has been revised to 1,000 mg/kg). Two hundred and twenty-nine of these 231 soil samples contained lead concentrations greater than the calculated HWAD lead background concentration of 16.7 mg/kg. A table of these results is included in Appendix C.

Three cone penetrometer test (CPT) soundings at SWMU C01a/01b found clayey silt to sand to a depth of 20 feet. Tt drilled six CPT borings and collected three soil samples from each boring. The borings were located where the surface soil samples showed the highest concentrations of lead so that they would evaluate the potential for lead impact in the subsurface worst-case scenarios. Lead was detected in all of these CPT subsurface soil samples, ranging from 6.9 mg/kg to 1,500 mg/kg. No other metals were analyzed for in the subsurface soil samples. A table of the results is included in Appendix C.

The one subsurface soil sample with the greatest lead concentration was collected at 2.5 feet bgs and contained 1,500 mg/kg; however, the collocated duplicate sample contained only 400 mg/kg of lead. Based on the other borings, the elevated lead concentration at a depth of 2.5 feet in soil boring SB06 appears to be an anomaly. The second greatest concentration of lead in a subsurface

soil sample was 250 mg/kg collected at 13 feet bgs. This concentration does not appear to be from leaching the surface soils. The two samples collected at six and nine feet bgs in the same boring contain only 30 and 6.9 mg/kg of lead, respectively. It is likely that the high lead concentration detected in the deeper sample at this boring is from a high concentration of lead soil sloughing into the boring from the surface during sampling.

In 1997, Tt collected and analyzed fourteen surface soil samples and two duplicate surface soil samples for metals other than lead. These samples were collected in areas where lead concentrations were high to assess if metals other than lead were released from the furnaces. These samples contained the highest concentrations of zinc (2,260 mg/kg to 412,000 mg/kg) and copper (1,970 mg/kg to 256,000 mg/kg), which are the metals that make up brass and that likely were released from munitions casings. Moderate concentrations were reported for aluminum (4,830 mg/kg to 41,600 mg/kg), barium (696 mg/kg to 43,200 mg/kg), iron (1,790 mg/kg to 11,000 mg/kg), magnesium (4,580 mg/kg to 32,900 mg/kg), and sodium (251 mg/kg to 48,300 mg/kg). Low concentrations were reported for antimony (62.3 mg/kg), arsenic (3 mg/kg to 16.5 mg/kg), cadmium (1.2 mg/kg to 95.7 mg/kg), total chromium (5 mg/kg to 129 mg/kg), cobalt (4.3 mg/kg), manganese (53.4 mg/kg to 262 mg/kg), mercury (0.21 mg/kg to 1.3 mg/kg), molybdenum (2.7 mg/kg), nickel (4 mg/kg to 37.6 mg/kg), potassium (1.320 mg/kg to 1,550 mg/kg), silver (0.52 mg/kg to 10.6 mg/kg), and vanadium (14.2 mg/kg). A table of these results is included in Appendix C.

Based on all of the remedial investigation data, lead was the only contaminant of concern at SWMU C01a/01b. The concentrations of lead were greater than the PCG, indicating that this site needed remediation before HWAD could recommend closure. The vertical extent of the lead-contaminated soil did not appear to exceed one foot bgs. The lateral extent of the high lead concentrations (greater than 1,000 mg/kg) in the surface soil extended approximately 300 feet to the northwest, 450 feet to the southeast, 375 feet to the southwest, and 300 feet to the northwest from Building 102-31.

Tt found the groundwater beneath SWMU C01a/01b not to be contaminated with lead (Tt 2001). Monitoring wells IRPMW28 and IRPMW29 are the nearest downgradient monitoring wells, and IRPMW30 and IRPMW31 are the nearest upgradient monitoring wells. Both pairs of wells are approximately 1,000 feet from the site. A table of the groundwater data for lead from these wells is included in Appendix A.

The detected lead concentrations in the groundwater samples from these wells during the basewide groundwater monitoring from 1997 through 1999 ranged from 1.1 μ g/l to 4.4 μ g/l. All of these concentrations are less than the HWAD groundwater action level for lead of 15 μ g/l. There also is little variance in the lead concentrations in the groundwater samples collected from the upgradient and downgradient wells. Also, elevated concentrations of lead in the soil at the site are found only to a depth of two feet bgs, with the shallowest groundwater at a depth of approximately 100 feet bgs. Based on these data, the groundwater beneath SWMU C01a/01b has not been affected by the elevated lead concentrations in the near-surface soils.

5.0 REMEDIATION

To assess a cost-effective remedial technique to mitigate the lead in the surface soils at SWMU C01a/01b, Tt completed a health-based risk assessment of the primary exposure pathways by ingestion and inhalation. They also evaluated innovative technologies, and selected one of these technologies for full-scale implementation.

Based on these studies, the approved technology for remediating SWMU C01a/01b was to treat those soils with the greatest concentrations of lead with a phosphate stabilization process so that the lead would not be leachable. Based on the ingestion scenario of the risk assessment, the stabilized soil could pose a human health threat; therefore, all of the treated soils were excavated and disposed of off-site but on-base. The excavated areas were backfilled with "clean" soil, and the site was reclaimed by hydroseeding the disturbed area with native species.

NDEP established a cleanup goal of 2,000 mg/kg as the maximum concentrations of lead that could remain in the surface soils at the site without being remediated. Based on the TCLP testing method for all of the treated soil, a lead treatment goal (LTG) of 5 mg/l of lead was established. Also established was a lead excavation goal (LEG) of 2,000 mg/kg of total lead as the maximum concentrations of lead in soils that could be left in the bottom of the excavations, and established a lead backfill goal of one-quarter of the LEG at 500 mg/kg as the maximum concentration of total lead in the soils imported to the site for backfill. Lastly, Tt established a soil boring goal equal to the LEG of 2,000 mg/kg to evaluate additional subsurface soil samples collected from soil borings after the treatment. A table of these remediation goals is included in Appendix A.

Tt treated in situ the lead contaminated soil at SWMU C01a/01b, which contained greater than 2,000 mg/kg of total lead within the top one foot of surface soils, with a phosphate chemical mixture. They excavated and disposed of the treated soil in a borrow pit at HWAD, and capped it. The site was backfilled and hydroseeded the excavations. Additional subsurface soil samples from borings were collected. Figure 1-1 shows the location of the onsite borrow pit where the treated soil was deposited.

The soil beneath the buildings and railroad tracks were assessed not to be contaminated because these structures were in place before the lead emissions were released. However, there was a potential for lead dust to be deposited on the ballast along the railroad tracks. The cost of removing these sections of track with the affected ballast was cost prohibitive and would have disrupted the HWAD mission. The NDEP agreed that the ballast could be treated in situ provided it was treated with twice the treatment dose as the phosphate mixture used to successfully treat the surface soils. This in situ treatment was successfully completed.

6.0 REMEDIATION RESULTS

The boundaries of the soil treatment area included all of the soils with concentrations greater than 2,000 mg/kg. The surface soils above a depth of one foot bgs were successful treated to less than the LTG. A table of the 55 soil samples collected to assess this treatment is included in

Appendix C. The TCLP results for these samples ranged from 0.0045 mg/l to 3.0 mg/l compared to the LTG of 5 mg/l.

Tt excavated and disposed of all of the soil with elevated concentrations of lead within the treatment boundary at SWMU C01a/01b. A table of the 63 soil samples collected from the excavations is included in Appendix C. The total lead concentrations for these samples ranged from 1.7 mg/kg to 1,280 mg/kg compared to the LEG of 2,000 mg/kg.

All of the soil used to backfill the excavations contained lead concentrations less than backfill goal. A table of the 15 soil samples collected from the backfill material is included in Appendix C. The total lead concentrations for these samples ranged from 2.4 mg/kg to 9 mg/kg, compared to the backfill goal of 500 mg/kg.

All of the subsurface soil samples contained lead concentrations less than the soil boring goal. A table of these 36 subsurface soil samples is included in Appendix C. The total lead concentrations for these samples ranged from 1.5 mg/kg to 113 mg/kg, compared to the soil boring goal of 2,000 mg/kg.

7.0 PUBLIC INVOLVEMENT

It is US Department of Defense and Army policy to involve the local community throughout the investigation process at an installation. To initiate this involvement, HWAD has established and maintains a repository at the local public library, which includes final copies of all past studies and other documents regarding environmental issues at HWAD. As future environmental documents are made available to HWAD, the repository will be updated.

HWAD has solicited community participation to establish a restoration advisory board (RAB). To date there has been insufficient response, and HWAD has not formed a RAB. HWAD has held open houses to inform the public of ongoing environmental issues and will continue to solicit community involvement. HWAD will establish a RAB should there be sufficient community interest.

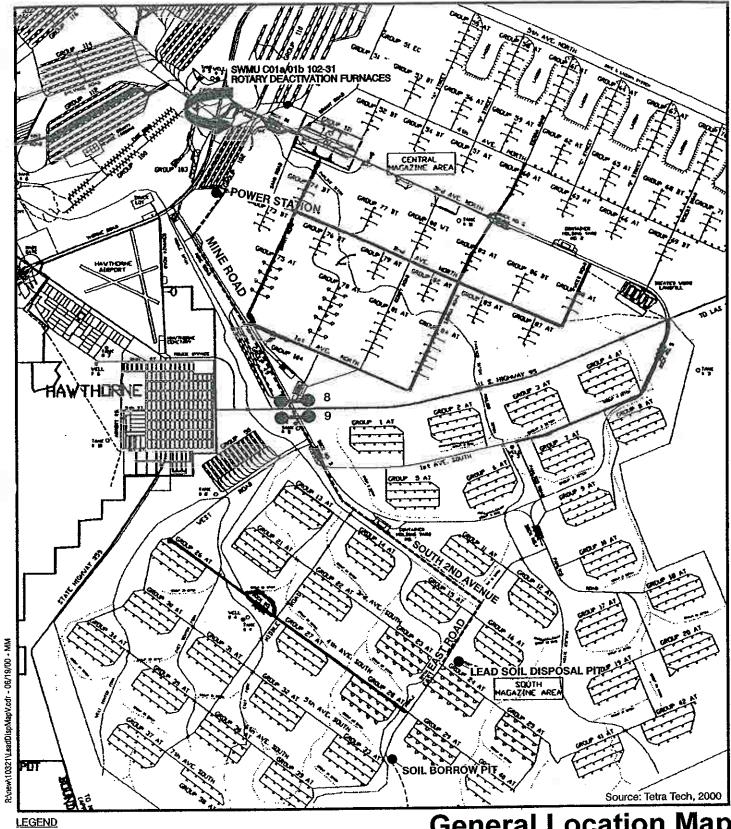

8.0 CONCLUSION

All of the remedial actions have been completed in accordance with the lead treatability study work plan to remediate SWMU C01a/01b. All of the samples collected during the various treatment actions were less than their respective remediation goals. The elevated lead concentrations at this site have been mitigated to levels that do not pose a threat to human health for on-site or off-site receptors. No additional investigations or remediation are necessary for this SWMU before closure is recommended; therefore, we recommend SWMU C01a/01b for closure, with the restrictions that the site remain only for industrial use, and that the site be documented on the HWAD master plan.

Site-specific Soil Treatment Goals SWMU C01a/01b - Building 102-31 Rotary Deactivation Furnaces

Treatment Activity	Goals			
Soil Stabilization	LTG—Leachable lead concentrations less than 5.0 mg/l by TCLP			
Excavation	LEG—Total lead concentration in soil left in place at less than 2,000 mg/kg			
Backfilling	Total lead concentrations of imported soil less than one-fourth of the LEG at 500 mg/kg			
Soil Borings	Total lead concentrations in the subsurface soils less than the LEG of 2,000 mg/kg			

TCLP = Toxicity Characteristic Leaching Procedure, as defined by Test Methods for Evaluating Solid Wastes, SW846, Method 1311 and EPA analytical method 6010.

NOTES ON COMPLETION OF FORM

- 1. GENERAL: This form may be used in the field or, as an office form to record and publish positions, descriptions, and related data.
- 2. FIELD USE OF FORM: The information required should be obtained and recorded AT THE STATION SITE. The field engineer should fill in only the information available and applicable to field use. In general, the geographic and grid positions, azimuths, distances, and elevations should not be filled in at field level except when the information is required for an immediate specific purpose.
- a. ORIGINAL DESCRIPTION OF NEW STATION: The type of mark used for the station, reference marks, and azimuth marks, and a description of each must be given in the text of the description. If a disk is used, the identity of the agency whose name is cast in the disk and all of the letters and numbers stamped on the mark which identify the organization establishing or setting the mark should be given. In many areas the use of disks is not desirable because of their loss, due to vandalism or superstition. Less conspicuous marks should be used under these conditions. This requires exact statements of the character of the marks. Information for all marks as to the elevation above or below ground and approximate elevation above or below nearby prominent features is important. At least three measurements within .01 foot should be made from the station to any permanent marks, features, or structures that would permit relocating the spot where an instrument was centered.

Good judgment should be exercised as to how far these measurements should be made. It is recommended that they be made to items which are not in the immediate vicinity of the station. Angles should also be turned to these items, particularly where no azimuth mark or marks have been established.

- b. VIEW: Provide information on height of tower or stand used in occupying or establishing the station and information on view from a normal tripod, i.e., a 50-foot tower was used at the station; view from a tripod height is clear to the south and east but is obstructed by rise in ground (by 50 foot trees) to the north and west.
- c. PHOTOGRAPHIC IDENTIFICATION: Provide when possible, two measurements from the station to natural or cultural features which might be visible on serial photography and a description of the terrain. If photographs are available identify the station thereon and note estimated accuracy of the identification.
- d. NOTES ON RECOVERED STATIONS: A diligent search should be made for ALL previously established stations in the vicinity and no station should be reported as destroyed unless conclusive evidence of destruction is present. A statement of the diligence of the search and reason for the nonrecovery of a previously established mark is required. If the spot where a station mark was located can be reproduced by measurement given in the description, the station is not destroyed. The reproduced spot should be tied in by azimuth and distance and the estimated accuracy of the reproduced location given. If a new mark is set in the exact location of a previously established but destroyed mark, the designation of the station should be identical with the original with only a new date added to its designation. If a new disk is set in the approximate location of the old station, the name should be preserved but the number "2" and a new date should be added.
